Algorithm

- Initialize board.
    - The board will be represented by a two-dimensional list with 9 rows and 9 columns.
    - Each element in the list will be a period, meaning it is not taken.
    - Initialize the board as an empty list.
    - For each of the 9 rows, initialize a list.
    - Then, use a for loop to add 9 elements.
    - Then, append this list to the board.
- Initialize a boolean variable that represents whether it is the first player's turn.
- A while loop will be used to handle each turn.
    - First, print the board.
    - Next, print out whether it is player one or player two's turn.
    - A while loop will be used to repeatedly get the input from the user until it is valid.
        - Get the input from the user as a string.
        - If the input is "stop", the game ends.
        - If the input is not "stop", extract the position from the string, then check if the position is valid.
        - Position is invalid if it does not have two components, is out of bounds or the space at that position is already taken (the element is not a period).
        - If the position is valid,
            - If it is the first player's turn, set the element at that position in the board to a blue circle.
            - If it is the second player's turn, set the element at that position in the board to a red circle.
            - Then, break out the loop
        - If the position is invalid, ask the user if they want to try again.
        - If the user inputs "Y", then ask for another input from the user.
        - If the user inputs "N", then skip their turn.
- After a player's turn, switch to the other player by inverting the boolean value representing whether it is the first player's turn.

Instructions

- The program will ask the user to input a position until it is valid.
- The user should input "stop" to exit the game.
- Position is (1, 1) at top left corner and (9, 9) at bottom right corner.
    - The first value, x, represents the row, and it increases from top to bottom.
    - The second value, y, represents the column, and it increases from left to right.
- The position is valid when there are two components, both x and y are between 1 and 9 inclusive, and that space is not already taken.
- The user should input the position as "x y" to continue, for example "2 4".

- If the position is not valid, the user will be asked if they want to try again, and they should input “Y” for yes or “N” or no.
- There is no winner so just have fun.
